- 1 We have placed  $n > 3$  cards around a circle, facing downwards. In one step we may perform the following operation with three consecutive cards. Calling the one on the center  $B$ , the two on the ends  $A$  and  $C$ , we put card  $C$  in the place of  $A$ , then move  $A$  and  $B$  to the places originally occupied by  $B$  and  $C$ , respectively. Meanwhile, we flip the cards  $A$  and  $B$ .

Using a number of these steps, is it possible to move each card to its original place, but facing upwards?

- 
- 2 Prove that if from any 2007 consecutive terms of an infinite arithmetic progression of integers starting with 2, one can choose a term relatively prime to all the 2006 other terms, then there is also a term amongst any 2008 consecutive terms relatively prime to the rest.

- 
- 3 Prove that any finite set  $H$  of lattice points on the plane has a subset  $K$  with the following properties:

- any vertical or horizontal line in the plane cuts  $K$  in at most 2 points,
  - any point of  $H \setminus K$  is contained by a segment with endpoints from  $K$ .
