- 1 A positive integer  $n$  is called *primary divisor* if for every positive divisor  $d$  of  $n$  at least one of the numbers  $d - 1$  and  $d + 1$  is prime. For example, 8 is divisor primary, because its positive divisors 1, 2, 4, and 8 each differ by 1 from a prime number (2, 3, 5, and 7, respectively), while 9 is not divisor primary, because the divisor 9 does not differ by 1 from a prime number (both 8 and 10 are composite). Determine the largest primary divisor number.

---

- 2 A set consisting of at least two distinct positive integers is called *centenary* if its greatest element is 100. We will consider the average of all numbers in a centenary set, which we will call the average of the set. For example, the average of the centenary set  $\{1, 2, 20, 100\}$  is  $\frac{123}{4}$  and the average of the centenary set  $\{74, 90, 100\}$  is 88. Determine all integers that can occur as the average of a centenary set.

- 3 Given a positive integer  $c$ , we construct a sequence of fractions  $a_1, a_2, a_3, \dots$  as follows:
  - $a_1 = \frac{c}{c+1}$
  - to get  $a_n$ , we take  $a_{n-1}$  (in its most simplified form, with both the numerator and denominator chosen to be positive) and we add 2 to the numerator and 3 to the denominator. Then we simplify the result again as much as possible, with positive numerator and denominator.
 For example, if we take  $c = 20$ , then  $a_1 = \frac{20}{21}$  and  $a_2 = \frac{22}{24} = \frac{11}{12}$ . Then we find that  $a_3 = \frac{13}{15}$  (which is already simplified) and  $a_4 = \frac{15}{18} = \frac{5}{6}$ .
  - (a) Let  $c = 10$ , hence  $a_1 = \frac{10}{11}$ . Determine the largest  $n$  for which a simplification is needed in the construction of  $a_n$ .
  - (b) Let  $c = 99$ , hence  $a_1 = \frac{99}{100}$ . Determine whether a simplification is needed somewhere in the sequence.
  - (c) Find two values of  $c$  for which in the first step of the construction of  $a_5$  (before simplification) the numerator and denominator are divisible by 5.

---

- 4 In triangle  $ABC$ , the point  $D$  lies on segment  $AB$  such that  $CD$  is the angle bisector of angle  $\angle C$ . The perpendicular bisector of segment  $CD$  intersects the line  $AB$  in  $E$ . Suppose that  $|BE| = 4$  and  $|AB| = 5$ .
  - (a) Prove that  $\angle BAC = \angle BCE$ .
  - (b) Prove that  $2|AD| = |ED|$ .

- 
- 5** Kira has 3 blocks with the letter  $A$ , 3 blocks with the letter  $B$ , and 3 blocks with the letter  $C$ . She puts these 9 blocks in a sequence. She wants to have as many distinct distances between blocks with the same letter as possible. For example, in the sequence  $ABCAABCBC$  the blocks with the letter  $A$  have distances 1, 3, and 4 between one another, the blocks with the letter  $B$  have distances 2, 4, and 6 between one another, and the blocks with the letter  $C$  have distances 2, 4, and 6 between one another. Altogether, we got distances of 1, 2, 3, 4, and 6; these are 5 distinct distances. What is the maximum number of distinct distances that can occur?
