- **1** Determine all integers $n \ge 1$ for which there exists n real numbers x_1, \ldots, x_n in the closed interval [-4, 2] such that the following three conditions are fulfilled:
 - the sum of these real numbers is at least n.
 - the sum of their squares is at most 4n.
 - the sum of their fourth powers is at least 34n.
 - (Proposed by Gerhard Woeginger, Austria)
- **2** Let ABC be a triangle with $90^{\circ} \neq \angle A \neq 135^{\circ}$. Let D and E be external points to the triangle ABC such that DAB and EAC are isoscele triangles with right angles at D and E. Let $F = BE \cap CD$, and let M and N be the midpoints of BC and DE, respectively.

Prove that, if three of the points A, F, M, N are collinear, then all four are collinear.

- Decide whether the integers 1, 2, ..., 100 can be arranged in the cells C(i, j) of a 10 × 10 matrix (where 1 ≤ i, j ≤ 10), such that the following conditions are fullfiled:
 i) In every row, the entries add up to the same sum S.
 ii) In every column, the entries also add up to this sum S.
 iii) For every k = 1, 2, ..., 10 the ten entries C(i, j) with i − j ≡ k mod 10 add up to S. (Proposed by Gerhard Woeginger, Austria)
- 4 Let *x*, *y*, *z* be positive real numbers. Prove that

$$\sum_{cyclic} \frac{xy}{xy + x^2 + y^2} \leq \sum_{cyclic} \frac{x}{2x + z}$$

(Proposed by efket Arslanagi, Bosnia and Herzegovina)
